ABSTRACT In this paper, we propose a joint beamforming and power-splitter optimization technique for simultaneous wireless power and information transfer in the downlink transmission of a multiple-input single-output (MISO) non-orthogonal multiple access (NOMA) system. Accordingly, each user employs a power splitter to decompose the received signal into two parts, namely, the information decoding and energy harvesting. The former part is used to decode the corresponding transmitted information, whereas the latter part is utilized for harvesting energy. For this system model, we solve an energy harvesting problem with a set of design constraints at the transmitter and the receiver ends. In particular, the beamforming vector and the power splitting ratio for each user are *jointly* designed such that the overall harvested power is maximized subject to minimum per-user rate requirements and the available power budget constraints at the base station. As the formulated problem turns out to be non-convex in terms of the design parameters, we propose a sequential convex approximation technique and demonstrate a superior performance compared to a baseline scheme.

INDEX TERMS Non-orthogonal multiple access (NOMA), energy harvesting, simultaneous wireless power and information transfer (SWIPT).

I. INTRODUCTION

Recently, non-orthogonal multiple access (NOMA) has been identified as a promising multiple access technique to meet the unprecedented data rate requirements in the fifth generation (5G) and beyond [1]. In the downlink transmission of power-domain NOMA, multiple users can be served in the same orthogonal resources (time and frequency) through employing superposition coding at the transmitter [2], [3].

The associate editor coordinating the review of this manuscript and approving it for publication was Xingwang $\text{Li}^{\textcircled{D}}$.

At the receiver ends, users with stronger channel conditions exploit successive interference cancellation (SIC) by detecting and subtracting the signals intended to the users with weaker channel conditions [4]. Due to its potential benefits and capabilities, NOMA has been incorporated with different spatial multiplexing techniques to facilitate its implementation in dense networks, while further improving the spectral efficiency [5]. These techniques include multiple-input multiple-output (MIMO) [6], [7], and multiple-input singleinput systems (MISO) [8], [9]. These NOMA integrated systems are considered as potential solutions to provide massive

⁶Institute for Digital Technologies, Loughborough University, London E15 2GZ, U.K.

connectivity in 5G and beyond while supporting the proliferation of Internet-of-Things (IoT) [10].

With the explosive growth of data traffic and number of devices, the environmental and economical concerns associated with the power consumption have become one of the major issues that need to be carefully addressed in the development of new technologies [11]. Among various research directions, one of the promising solutions considered in the literature is the efficient utilization of the available power resources to maximize the overall energy efficiency (EE) of the communication systems [12], [13]. This EE maximization approach provides the flexibility to strike a good balance between the achieved data rate of a system and the corresponding power consumption [12]. Secondly, owing to the fact that non-green power resources have undesirable impacts on both environment and economy, recent solutions promote to employ the green renewable energy resources including wind and solar power [11]. Particularly, recent research activities have focused on the novel energy harvesting technique with simultaneous wireless power and information transfer (SWIPT) technology. This technology has been identified as one of the potential solutions to address the excessive power consumption issues in future wireless networks [14].

The underlying concept of SWIPT is to utilize the RF signal to simultaneously transmit information and energy through the wireless medium [14], [15]. Theoretically, this can be accomplished by decomposing the received signal into two parts at the receiver end, namely, information decoding (ID) and energy harvesting (EH) [16]. This decomposition is performed by employing either the power splitting (PS) technique or the time switching technique (TS) [17]. Although, the PS techniques impose additional hardware complexity at the receiver end, it is preferred over TS techniques due to flexibility of practical implementations [16], [17]. This is due to the fact that TS demands a tight synchronization between the transmitter and receiver [18]. Furthermore, the receiver requires the perfect instantaneous timing information for the EH and ID, which is challenging to achieve in practice, especially in real-time delay-tolerant applications. SWIPT is expected to play a crucial role in future generations of wireless networks. We provide a brief discussion on some of its applications. Firstly, SWIPT has the potential to wirelessly charge various medical sensors inside a human body which will avoid any need for physical wired connections. Replacing or charging these medical sensors is either expensive or even impractical due to invasive surgery requirements [19]. The SWIPT technology will become a potential way of providing power supply to wireless-powered sensor networks (WPSN) such as those deployed in buildings for structural monitoring [20]. Furthermore, SWIPT can be a viable solution for providing power supply for satellite communication systems [19], [20]. In particular, satellites can simultaneously transmit power and information for low-power-consumed mobile base stations including unmanned aerial vehicles [20]. Furthermore, EH through SWIPT can be utilized to provide power supply for the satellites [20], [21]. In cooperative networks, the EH through SWIPT can enhance the performance of users with weaker channel conditions [22], [23]. In addition, SWIPT can be an essential energy source in lowpower IoT wireless systems, where a large number of energyhungry devices with the limitation of battery size has to be always charged to support different wireless applications and services [24], [25]. In fact, SWIPT is an appealing solution to extend billions of IoT devices' lifetime while achieving self-sustainability [26] [27], [28]. Hence, EH through SWIPT would undoubtedly make fundamental impacts on the future green communications [29].

A. LITERATURE REVIEW

In order to fully exploit the potential benefits offered by the combined NOMA and SWIPT, several research studies have been performed recently. In particular, different resource allocation techniques have been proposed for SWIPT-based NOMA systems to realize their capabilities. For example, the authors in [30] have considered a single-input singleoutput (SISO) TS-based SWIPT system in which time and power are jointly allocated to maximize the overall EE of the system with minimum-rate and minimum harvested-power constraints. Furthermore, a sum-rate maximization problem for SWIPT-based MISO-NOMA system has been considered in [31], where the users could either harvest energy or receive the corresponding information. Similarly, the authors in [32] have considered the sum-rate maximization for a SWIPT-based MISO-NOMA system with a PS approach where two users are grouped into a cluster. In each cluster, the near-user has the potential to simultaneously harvest energy and decode information, whereas the weaker user can decode only its corresponding information. In [33], a power minimization problem has been considered for a SWIPTbased MISO-NOMA cognitive network. Robust beamforming algorithms for maximizing the weighted sum rate and for minimizing the total power consumption have been investigated in [34]. A cooperative transmission of SWIPT based MISO-NOMA has been considered in the downlink in [35]. In this cooperative communication scenario, the stronger users utilize the harvested energy to forward the signals of the weaker users after decoding them through SIC [35], [36]. In fact, the strong users operate as relays to further improve the performance of the weaker users.

B. CONTRIBUTIONS

In SWIPT, the received RF signal, including both the useful and the interference components, is utilized to harvest energy. In particular, undesired interference is converted into a useful resource in SWIPT-based communication systems [23]. The SWIPT technology perfectly aligns with the fundamental concept of NOMA as the users are served by sharing the same orthogonal resources [37]. This non-orthogonal resource sharing introduces more interference at the receivers compared to that of the conventional orthogonal multiple access systems. The additional interference can be exploited to harvest energy with SWIPT technology. Therefore, SWIPT

perfectly suits the NOMA systems for offering complementary benefits to the users [3]. Furthermore, the interference and the additional degrees of freedom with multiple-antenna techniques can also support the core concept of SWIPT [38]. Motivated by the promising capabilities of combining a multi-antenna NOMA system with the SWIPT technique, we consider a SWIPT based MISO-NOMA system. For this system model, we propose a joint beamforming and power-splitting optimization technique for a non-cooperative transmission of SWIPT based MISO-NOMA system. In particular, the EH capabilities of the MISO-NOMA system are considered with users having the ability to decode information and harvest energy simultaneously. This scenario perfectly aligns with the requirements of WPSN, in which a set of sensors demands to be always charged through maximizing the harvested energy while achieving minimumrate constraints [19]. The developed optimization problem turns out to be non-convex in its original form. Hence, a sequential convex approximation (SCA) is adopted to tackle this non-convexity issue. Additionally, we investigate the feasibility of the problem prior to solving it. Furthermore, we investigate the efficiency of the proposed SCA technique by evaluating its performance. The performance of the proposed MISO-NOMA beamforming design is evaluated versus a baseline MISO system with zero forcing beamforming (ZFBF) in terms of the overall harvested energy [39].

The remainder of the paper is organized as follows. Section II introduces the system model of a SWIPT based MISO-NOMA system and formulates the harvested power maximization problem. Section III provides the technical details of the proposed algorithms to examine the feasibility and present the solution of the original optimization problem. Section IV presents simulation results, which demonstrate the effectiveness of the proposed beamforming design and evaluate its performance versus a baseline design. Finally, conclusions are drawn in Section V.

C. NOTATIONS

We use lower case boldface letters for vectors and upper case boldface letters for matrices. $(\cdot)^H$ denotes complex conjugate transpose. $\Re(\cdot)$ and $\Im(\cdot)$ stand for real and imaginary parts of a complex number, respectively. The symbols \mathbb{C}^N and \mathbb{R}^N denote *N*-dimensional complex, and real spaces, respectively. $|| \cdot ||_2$ and $| \cdot |$ represent the Euclidean norm of a vector and absolute value of a complex number, respectively.

II. SYSTEM MODEL AND PROBLEM FORMULATION

A. SYSTEM MODEL

We consider the downlink transmission of a MISO-NOMA system, in which a BS with N transmit antennas communicates simultaneously with all K single-antenna users. Each user performs energy harvesting and decoding as shown in Fig. 1. The BS encodes the symbol intended to each user by multiplying with its corresponding beamforming vector.

FIGURE 1. SWIPT receiver with PS technique.

Therefore, the transmitted signal from the BS is given by

$$\mathbf{x} = \sum_{i=1}^{K} \mathbf{b}_i s_i,\tag{1}$$

where s_i and $\mathbf{b}_i \in \mathbb{C}^{N \times 1}$ denote the symbol intended for the i^{th} user (U_i) and the corresponding beamforming vector, respectively. The received signal at U_k can be written as

$$y_k = \mathbf{h}_k^H \sum_{j=1}^K \mathbf{b}_j s_j + n_k, \qquad (2)$$

where n_k is zero mean circularly symmetric complex additive white Gaussian noise (AWGN) with variance σ_i^2 , while $\mathbf{h}_k \in \mathbb{C}^{N \times 1}$ represents the channel vector between the BS and U_k . This channel vector can be expressed as

$$\mathbf{h}_k = (\frac{1}{d_k})^{\phi} \mathbf{g}_{\mathbf{k}},\tag{3}$$

where d_k denotes the distance (in meter) between the BS and U_k , ϕ is the path loss exponent, \mathbf{g}_k represents the small scale fading coefficient, assumed to be complex-valued normal distributed with zero mean and unity variance. Furthermore, we assume that each user has a power splitter such that a fraction (β_k) of y_k is utilized to decode the data in the ID stage, i.e., $0 \le \beta_k \le 1$. In addition, the fraction $(1 - \beta_k)y_k$ is used to harvest the energy through the EH circuit, as depicted in Fig. 1. We provide further details of the PS technique in the following discussions.

1) ID STAGE

The signal at the output of the ID stage \tilde{y}_k is given as $\tilde{y}_k = \sqrt{\beta}y_k + \tilde{n}_k$, where y_k is corrupted by the AWGN \tilde{n}_k . This noise is due to processing of y_k in the ID circuit [16]. In particular, \tilde{n}_k is AWGN with variance $\tilde{\sigma}_k^2$. Based on the fundamental concepts of NOMA, the users with stronger channel conditions have the capability to decode and subtract the signals intended for the weaker users through employing SIC [40]. Therefore, users' ordering based on the channel conditions is a crucial factor which significantly influences the performance of NOMA systems. Based on this key fact, we order the users such that U_1 has the strongest channel condition. This can be expressed as follows:

$$||\mathbf{h}_{1}||_{2}^{2} \ge ||\mathbf{h}_{2}||_{2}^{2} \ge \cdots \ge ||\mathbf{h}_{K}||_{2}^{2}.$$
 (4)

Following this user ordering in (4), U_k has the capability to sequentially decode and subtract the symbols of the weaker users $U_{k+1}, U_{k+2} \cdots U_K$, prior to decoding its own signal. The user U_k performs SIC by firstly decoding the signal of the weakest user, and then subtracts the corresponding portion of the received signal. Hereafter, the stronger users refer to the users with stronger channel conditions. This SIC process is continued with the other weaker users (i.e., $U_{K-1}, \cdots, U_{k+1}, U_k$) until y_{k+1} is correctly decoded and subtracted from the received signal [2]. Then, U_k decodes its own signal, and the received signal at U_k after employing SIC technique with other weaker users can be written as

$$\bar{\mathbf{y}}_k = (\sqrt{\beta_k}) \left(\mathbf{h}_k^H \sum_{i=1}^{k-1} \mathbf{b}_i s_i + n_k \right) + \tilde{n}_k.$$
 (5)

The received signal-to-noise and interference ratio (SINR) of the decoding signal intended for the weaker user U_j , i.e., $j \ge k$, at U_k (SINR^k_i) can be written as

$$\operatorname{SINR}_{j}^{k} = \frac{\beta_{k} |\mathbf{h}_{k}^{H} \mathbf{b}_{j}|^{2}}{\beta_{k} (\sum_{z=1}^{j-1} |\mathbf{h}_{k}^{H} \mathbf{b}_{z}|^{2} + \sigma_{k}^{2}) + \hat{\sigma}_{k}^{2}}, \quad \forall k \in \mathcal{K}.$$
(6)

Note that $\mathcal{K} = \{1, 2, \dots, K\}$ defines the set of all users. Furthermore, the signal of U_j is successfully decoded at $U_1, U_2 \cdots U_j$ if-and-only-if the SINR of decoding this signal is larger than a certain pre-defined threshold. Then, this should be satisfied at all other stronger users in order to correctly decode the signal. As a result [2],

$$\operatorname{SINR}_{j} = \min \left\{ \operatorname{SINR}_{j}^{k} \right\}_{k=1}^{j}, \quad \forall j \in \mathcal{K}.$$
(7)

Note that the SIC process could not be practically implemented unless the SINR of the decoding signal intended for the weaker user signal at U_k (SINR^k_j) is higher than that of the stronger users. This can be guaranteed by imposing the following constraints [41]:

$$\mathbf{h}_{k}^{H}\mathbf{b}_{K}|^{2} \geq |\mathbf{h}_{k}^{H}\mathbf{b}_{K-1}|^{2} \geq \cdots |\geq |\mathbf{h}_{k}^{H}\mathbf{b}_{1}|^{2}, \quad \forall k \in \mathcal{K}.$$
(8)

It is worth mentioning that the constraint in (8) is referred to as SIC constraint in the literature.

With this successful implementation of SIC, the achieved rate at U_j can be expressed as

$$R_j = B_w \log(1 + \text{SINR}_j), \quad \forall j \in \mathcal{K},$$
(9)

where B_w denotes the available bandwidth. Additionally, the achieved sum rate of the system can be defined as

$$R = \sum_{j=1}^{K} R_j. \tag{10}$$

2) EH STAGE

The EH circuit utilizes the EH part to harvest energy at the EH stage. The received signal after EH stage can be written as

$$\hat{y}_k = \sqrt{1 - \beta_k} y_k + \hat{n}_k, \tag{11}$$

where \hat{n}_k is the AWGN with zero mean and variance $\hat{\sigma}_k^2$ introduced by the processing of y_k in the EH stage. The EH circuit mainly consists of a matching network, a radio frequency to direct current (RF-DC) and a storage unit [18]. By ignoring the noise power (i.e., $\hat{\sigma}_k^2$ and σ_k^2) [42], the harvested power at U_k can be expressed as [43]

$$\mathbf{P}_{k,H} = \eta \sum_{i=1}^{K} (1 - \beta_k) |\mathbf{h}_k^H \mathbf{b}_i|^2, \qquad (12)$$

where η denotes the efficiency of the RF-DC converter in the EH stage. It is worth mentioning that the practical experiments reveal that the harvested energy first grows almost linearly with the input power, and then saturates when the input power reaches to a certain level [43], [44]. In fact, several models have been considered to reflect such nonlinear characteristics of the EH circuit, including non-linear EH (NL-EH) model based on the logistic (sigmoid) function [34]. In particular, it was shown that the non-linear model can provide higher performance gain than that of the linear model [45], [46]. As such, the performance gains of linear EH model can be viewed as a benchmark performance for the techniques developed with non-linear EH model. To this end, a linear model is considered in this paper to establish a benchmark performance. Hence, the overall harvested power by all the users in the above MISO-NOMA system can be written as

$$\mathbf{P}_{H} = \eta \sum_{k=1}^{K} \sum_{i=1}^{K} (1 - \beta_{k}) |\mathbf{h}_{k}^{H} \mathbf{b}_{i}|^{2}.$$
 (13)

Note that the total harvested energy at all users can be defined as

$$\mathbf{E}_{H} = T(\eta \sum_{k=1}^{K} \sum_{i=1}^{K} (1 - \beta_{k}) |\mathbf{h}_{k}^{H} \mathbf{b}_{i}|^{2}),$$
(14)

where T denotes the transmission time.¹ It is worth pointing out that our analysis is performed based on the harvested power.

B. PROBLEM FORMULATION

We investigate the energy harvesting capabilities of the MISO-NOMA system. A joint design of the beamforming vectors $\{b_i\}_{i=1}^{K}$ and the PS ratios $\{\beta_i\}_{i=1}^{K}$ is considered to maximize the harvested power P_H with a minimum-rate requirement at each user, referred to as R_k^{min} . This requirement ensures that the received power is shared between ID and EH instead of being fully used for EH. It is worth mentioning that the ignorance of this constraint leads to a significant degradation in the achieved rate at the corresponding user. This minimum rate requirement can be formulated as the following constraint in terms of SINR:

$$\operatorname{SINR}_k \ge \operatorname{SINR}_k^{\min}, \quad \forall k \in \mathcal{K},$$
 (15)

 1 In this paper, T is assumed to be one, and thus, energy and power carry the same meaning.

where $\text{SINR}_{k}^{min} = 2^{\text{R}_{k}^{min}} - 1$. Furthermore, the beamforming design should consider the available power budget at the BS, P^{A} , which can be defined through the following constraint:

$$\sum_{k=1}^{K} ||\mathbf{b}_k||_2^2 \le \mathbf{P}^A.$$
 (16)

With the above constraints and the SIC constraints in (8), the design parameters (i.e., $\{\beta_i\}_{i=1}^K$ and $\{b_i\}_{i=1}^K$) can be determined by solving the following optimization problem:

$$OP_{H}: \underset{\{\mathbf{b}_{k},\beta_{k}\}_{k=1}^{K}}{\text{maximize}} \eta \sum_{k=1}^{K} \sum_{i=1}^{K} (1-\beta_{k}) |\mathbf{h}_{k}^{H} \mathbf{b}_{i}|^{2}$$
(17a)

subject to $\text{SINR}_k \geq \text{SINR}_k^{min}, \quad \forall k \in \mathcal{K}, (17b)$

$$\sum_{k=1}^{K} ||\mathbf{b}_k||_2^2 \le \mathbf{P}^A,\tag{17c}$$

There are a number of challenges associated with solving the optimization problem OP_H defined in (17). First, the feasibility of the problem should be examined prior to solving OP_H to ensure that the required minimum-rates can be achieved with the given power budget. The second challenge is the non-convexity of the objective function and the constraints in (17b) and (17d). This means that OP_H is a nonconvex optimization problem, which could not be directly solved via available software. Finally, once the problem is solved, an evaluation process has to be carried out to verify the effectiveness of the obtained solution. With these challenges, we develop a comprehensive methodology to determine a feasible solution in the following section.

III. THE PROPOSED METHODOLOGY

In this section, we first examine the feasibility of the optimization problem OP_H . Then, we propose an efficient algorithm to solve the problem OP_H and determine the design parameters, i.e., $\{b_i, \beta_i\}_{i=1}^K$. Finally, we evaluate the effectiveness of the proposed approach through numerical simulations.

A. FEASIBILITY OF OP_H

It is apparent that the optimization problem OP_H is only feasible when the available power budget (i.e., \mathbf{P}^A) is sufficient to achieve the minimum rate requirements of all users. Otherwise, the problem becomes infeasible. Once the feasibility of the optimization problem is verified, it can be solved. In order to examine the feasibility, we first assume that all the users are completely switched to ID mode (i.e., $\beta_i = 1, \forall i$). Then, we evaluate the corresponding required minimum transmit power (P_t^{min}) to meet the minimum rate requirements. In this setting, when P_t^{min} exceeds \mathbf{P}^A , the harvested power maximization problem OP_H turns out to be infeasible. As such, we evaluate P_t^{min} through solving the following power minimization (P-Min) problem:

S

$$OP_P: \mathbf{P}_t^{min} = \underset{\{\mathbf{b}_i\}_{i=1}^K}{\operatorname{minimize}} \sum_{k=1}^K ||\mathbf{b}_i||_2^2$$
(18a)

subject to
$$\text{SINR}_k \ge \text{SINR}_k^{min}, \ \forall k \in \mathcal{K}, \ (18b)$$

(8). (18c)

Note that OP_P was solved in [6], however, the solution of this non-convex problem can be found throughout this paper. If $P_t^{min} \leq P^A$, then the optimization problem OP_H is obviously feasible and worthy to solve at least under the worst-case scenario, i.e., the users can achieve their minimum rate requirements without EH. On the other hand, if $P_t^{min} > P^A$, then OP_H becomes infeasible and cannot be solved with the available power budget. In this case, the BS has two choices: either to minimum rate requirements and does not transmit, or to maximize the sum rate of all users without considering the minimum rate requirements. In this work, we alternatively design the beamforming vectors to maximize the sum rate for the case of $P_t^{min} > P^A$. These beamforming vectors can be determined through solving the following sum-rate maximization (SRM) problem:

$$OP_R$$
: maximize $\sum_{\{\mathbf{b}_i\}_{i=1}^K}^K \mathbf{R}_k$ (19a)

subject to
$$\sum_{i=1}^{K} ||b_i||_2^2 \le \mathbf{P}^A, \tag{19b}$$

Note that the solution of the SRM problem OP_R can be found in the context of this paper, whereas the full detailed solution is available in [41] [47].

(8)

B. THE PROPOSED ALGORITHM TO SOLVE OPH

We consider a feasible optimization problem OP_H and its feasibility can be validated through the feasibility check introduced earlier in this section. Thus, it is worthy to solve the feasible OP_H . However, there are a number of issues that needs to be addressed before solving OP_H , including the non-convexity, the joint design of the beamforming vectors, and the PS ratio. In particular, the OP_H in (17) is a nonconvex problem due to the non-convex objective function and the constraints in (17b) and (17d), respectively. Therefore, the non-convex optimization problem OP_H cannot be solved directly using the existing software. We deal with these nonconvexity issues by developing an iterative algorithm based on the SCA technique. In this SCA algorithm, each nonconvex term is approximated with a lower convex-concave (linear) approximation using the first-order Taylor series, and the original optimization problem is iteratively solved [48]. In particular, the SCA algorithm has been widely utilized to solve several resource allocation problems in the literature [49], [50] and [51]. We start handling the non-convexity of the objective function of OP_H by decomposing it into two

parts: $\sum_{i=1}^{K} (1 - \beta_k)$ and $|\mathbf{h}_k^H \mathbf{b}_i|_2^2$. Then, each part is bounded by a slack variable as follows:

$$|\mathbf{h}_{k}^{H}\mathbf{b}_{i}|^{2} \ge \alpha_{k,i}, \quad \forall k \in \mathcal{K}, \forall i \in \mathcal{K},$$
 (20a)

$$1 - \beta_k \ge \Gamma_k^2, \quad \forall k \in \mathcal{K}.$$
 (20b)

With these new slack variables, we define the objective function in OP_H as follows:

$$\Gamma_k^2 \alpha_{i,k} \ge \chi_{i,k}, \quad \forall k \in \mathcal{K}, \ \forall i \in \mathcal{K}.$$
(21)

Without loss of generality, the objective function of OP_H can be equivalently expressed as

(17*a*)
$$\Leftrightarrow$$

$$\begin{cases} \text{maximize} \quad \eta \sum_{k=1}^{K} \sum_{i=1}^{K} \chi_{i,k} \quad (22a) \\ \text{subject to} \quad (20a) \quad (20b) \quad (21) \quad (22b) \end{cases}$$

u subject to
$$(20a), (20b), (21).$$
 (22b)

Obviously, the non-convex objective function in the original problem OP_H has been replaced by the lower bounded slack variable $\chi_{i,k}$. However, the non-convex constraints (20a), (20b), and (21) are now included in OP_H . Therefore, we handle these non-convex constraints in the following discussion. In fact, the non-convexity of (20a) can be handled by approximating its left-hand side with a lower convex-concave (linear) expression using the first-order Taylor series as follows:

$$\alpha_{i,k}^{(t+1)} \ge \left\| \begin{bmatrix} \varrho_{i,k}^{(t)}, & \rho_{i,k}^{(t)} \end{bmatrix} \right\|_{2}^{2} + 2 \begin{bmatrix} \varrho_{i,k}^{(t)}, & \rho_{i,k}^{(t)} \end{bmatrix}^{T} \\ \times \begin{bmatrix} \varrho_{i,k}^{(t+1)} - \varrho_{i,k}^{(t)}, & \rho_{i,k}^{(t+1)} - \rho_{i,k}^{(t)} \end{bmatrix}, \quad (23)$$

where

$$\boldsymbol{\varrho}_{i,k}^{(t)} = \Re\{\mathbf{h}_i^H \mathbf{b}_k^{(t)}\}, \quad \forall k \in \mathcal{K}, \forall i \in \mathcal{K},$$
(24a)

$$\rho_{i,k}^{(t)} = \Im\{\mathbf{h}_i^H \mathbf{b}_k^{(t)}\}, \ \forall k \in \mathcal{K}, \forall i \in \mathcal{K}.$$
(24b)

Note that the superscript $(\cdot)^{(t)}$ denotes the approximation at the t^{th} iteration Similarly, the non-convexity of the constraint in (20b) can be handled using the same technique that was utilized for the previous constraint. With this approximation, the non-convex constraint in (20b) can be equivalently written as

$$1 - \beta_k \ge \Gamma_k^{2^{(t)}} + 2\Gamma_k^{(t)}(\Gamma_k^{(t+1)} - \Gamma_k^{(t)}). \forall k \in \mathcal{K}.$$
 (25)

Now, we approximate the left side of the inequality (21) as follows:

$$\Gamma_k^{2(t)} \alpha_{i,k}^{(t)} + \Gamma_k^{2(t)} \left(\alpha_{i,k}^{(t+1)} - \alpha_{i,k}^{(t)} \right)$$

$$+ 2\Gamma_k^{(t)} \alpha_{i,k}^{(t)} \left(\Gamma_k^{(t+1)} - \Gamma_k^{(t)} \right) \ge \chi_{i,k}, \ \forall k \in \mathcal{K}, \ \forall i \in \mathcal{K}.$$
(26)

To summarize, we have replaced the non-convex objective function of OP_H by the convex slack variable, (22a), subject to the convex constraints provided in (23), (25), and (26).

Next, we handle the non-convex constraints in (17b) and (17d) in the original OP_H problem. By introducing the slack variable κ_k , the minimum SINR constraint in (17b) can be decomposed into a set of constraints as follows:

$$\beta_i |\mathbf{h}_i^H \mathbf{b}_k|^2 \ge \gamma_k \kappa_k^2, \quad \forall k, i \le k,$$
(27a)

$$\kappa_k^2 \ge \beta_i (\sum_{z=1}^{k-1} |\mathbf{h}_i^H \mathbf{b}_z|^2 + \sigma_i^2) + \hat{\sigma}_i^2, \quad \forall k, i \le k,$$
(27b)

where $\gamma_k = \text{SINR}_k^{min}$. The non-convexity of the constraint in (27a) can be handled through incorporating new slack variables, namely Υ_j and $\varpi_{i,k}$, such that this constraint can be reformulated as the following set of constraints:

$$\beta_i \ge \Upsilon_i^2, \quad \forall i,$$
 (28a)

$$\Upsilon_i^2 \alpha_{k,i} \ge \varpi_{k,i}, \quad k \in \mathcal{K}, i \le k,$$
(28b)

$$\varpi_{k,i} \ge \gamma_k \kappa_k^2, \quad k \in \mathcal{K}, i \le k.$$
(28c)

By reformulating each non-convex term with a linear approximation using the first-order Taylor series, the non-convex constraints in (28) can be transformed into the following convex constraints:

$$\beta_{i} \geq \Upsilon_{i}^{2^{(t)}} + 2\Upsilon_{i}^{(t)}(\Upsilon_{i}^{(t+1)} - \Upsilon_{i}^{(t)}), \quad \forall i,$$
(29a)
$$\Upsilon_{i}^{2^{(t)}}\alpha_{k,i}^{(t)} + \Upsilon_{i}^{2^{(t)}}\left(\alpha_{k,i}^{(t+1)} - \alpha_{k,i}^{(t)}\right) + 2\alpha_{k,i}^{(t)}\Upsilon_{i}^{(t)}\left(\Upsilon_{i}^{(t+1)} - \Upsilon_{i}^{(t)}\right) \geq \varpi_{k,i}, k \in \mathcal{K}, i \leq k,$$
(29b)

$$\overline{\omega}_{k,i} \ge \gamma_k \Big(\kappa_k^{2^{(t)}} + 2\kappa_k^{(t)} (\kappa_k^{(t+1)} - \kappa_k^{(t)}) \Big), k \in \mathcal{K}, i \le k.$$
(29c)

Similarly, the non-convex constraint in (27b) can be approximated by the following convex constraint:

$$\kappa_{k}^{2(t)} + 2\kappa_{k}^{(t)}(\kappa_{k}^{(t+1)} - \kappa_{k}^{(t)}) \\ \geq \sum_{z=1}^{k-1} \overline{\varpi}_{i,z} + \sigma_{i}^{2} \left(\Upsilon_{i}^{2(t)} + 2\Upsilon_{i}^{(t)}(\Upsilon_{i}^{(t+1)} - \Upsilon_{i}^{(t)}) + \hat{\sigma}_{i}^{2}, \quad k \in \mathcal{K}, \ i \leq k.$$
(30)

Based on the above approximations, the non-convex constraint in (17b) is transformed into the following set of convex constraints:

$$(17b) \Leftrightarrow (29a), (29b), (29c), (30).$$
 (31)

Finally, the SIC constraint in (17d) can be formulated as a convex one by replacing each term in the inequality by the lower slack variable $\alpha_{i,k}$. Therefore, this constraint can be written as

$$\alpha_{k,K} \ge \alpha_{k,K-1} \ge \cdots \ge \alpha_{k,1}, \quad \forall k \in \mathcal{K}.$$
(32)

With these multiple slack variables, the approximated convex form of the original non-convex problem OP_H can be defined as follows:

$$\hat{OP}_{H}$$
: maximize $\eta \sum_{k=1}^{K} \sum_{i=1}^{K} \chi_{i,k}$
subject to (17*c*), (23), (25), (26), (31), (32),

where Π includes all the design parameters, such that $\Pi = \{\mathbf{b}_k, \alpha_{j,k}, \Upsilon_k, \Gamma_k, \kappa_k, \beta_k, \varrho_{j,k}, \rho_{j,k}, \chi_{j,k}, \overline{\varpi}_{i,k}\}_{k=1}^K$.

It is clear that the optimization problem $O\hat{P}_H$ is iteratively solved, such that the obtained solutions at the t^{th} iteration are used as initialization for the next $t + 1^{th}$ iteration. Considering this iterative algorithm, three important issues need to be clearly addressed. First, the iterative algorithm based solution requires appropriate selection of the initial parameters, i.e., $\Pi^{(0)}$. Note that a random selection of the initial parameters might make the \hat{OP}_H infeasible. The inappropriate selection of initial parameters has a direct impact on the convergence speed of the iterative algorithm. Secondly, with this SIC algorithm, the solution is obtained and the algorithm is terminated when the difference between two successive solutions is less than a pre-defined accuracy. Finally, as the original nonconvex optimization problem OP_H is approximated by the convex one \hat{OP}_H , it is important to validate the effectiveness of the proposed iterative algorithm. All the above issues are addressed in the following subsections.

C. INITIALIZATION, COMPLEXITY ANALYSIS AND PERFORMANCE EVALUATION

1) Initial PARAMETERS AND Convergence

As highlighted in the previous subsection, an inappropriate selection of the initial parameters $\Pi^{(0)}$ for the proposed SCA algorithm might make the original problem infeasible and not provide a solution. Therefore, we present a systematic approach to select the initial parameters. As such, the beamforming vectors obtained through solving OP_P , $\{\mathbf{b}_i^{mn}\}_{i=1}^K$, are utilized to initialize the parameters, such as $\{\mathbf{b}_i^{(0)}\}_{i=1}^K = \{\mathbf{b}_i^{min}\}_{i=1}^K$. Consequently, all slack variables can be determined by $\mathbf{b}_i^{(0)}$. mined by substituting $\{\mathbf{b}_{i}^{(0)}\}_{i=1}^{K}$ at each inequality that defines the corresponding slack variables. For example, the initial slack variable $\alpha_{k,i}^{(0)}$ can be determined as follows:

$$\boldsymbol{\alpha}_{k,i}^{(0)} = \mathbf{h}_k^H \mathbf{b}_i^{(0)}, \quad \forall k, \; \forall i.$$
(34)

Additionally, this initialization not only ensures the feasibility of the proposed SCA algorithm, but also speeds up its convergence to yield a feasible solution. This will be confirmed through simulation results in Section IV. Note that the proposed iterative algorithm terminates when the absolute difference between two successive solutions is less than a predefined threshold ν . As such, the corresponding solution is denoted as $\Pi^{(*)}$. We summarize the proposed algorithm in Algorithm 1.

2) COMPLEXITY ANALYSIS OF THE PROPOSED SCA **TECHNIQUE**

The original optimization problem OP_H is solved using an iterative SCA algorithm, in which different approximations and slack variables are introduced. In particular, the solution of OP_H is obtained by iteratively solving the approximated convex optimization problem $O\hat{P}_H$. With linear objective function and constraints, the problem $O\hat{P}_H$ turns out to be a linear program which is solved using the Dantzig's simplex method [52]. Note that the number of arithmetic operations required to solve a linear program cannot be exactly defined;

Algorithm 1 Harvested Power Maximization Algorithm

Step 1: Feasibility check examination.

- 1) Evaluate \mathbf{P}_{t}^{min} through solving OP_{P} .

 - a) If P^{min}_t > P^A ⇒ OP_H is infeasible Find beamforming vectors that solve OP_R.
 b) If P^{min}_t ≤ P^A ⇒ OP_H is feasible
 - Go to Step 2.
- Step 2: Evaluating $\Pi^{(*)}$.
 - 1) Initialization (i.e., $\Pi^{(0)}$).
 - 2) **R**epeat
 - a) Solve the optimization problem $O\hat{P}_H$.
 - b) Until the required accuracy is achieved.

Step 3: End of the Algorithm.

however, its complexity for one iteration is bounded by an order $\mathcal{O}(n^2m)$, where m and n are the numbers of constraints and the optimization parameters, respectively [52]. Considering this, the complexity of solving the original optimization problem OP_H is bounded by $O\left(n^2 m \log(\frac{1}{\nu})\right)$, where $m = K^3 + 6K^2 + K + 1$ and $n = 7K^2 + 5K$. Note that the computational complexity increases as the pre-defined threshold ν decreases.

3) PERFORMANCE VALIDATION

In this subsection, we discuss how to evaluate the performance of the proposed algorithm. This evaluation can be carried out by comparing the performance of the proposed algorithm with that that of an exhaustive search. However, note that the exhaustive search is not suitable for practical implementation due to its high computational complexity. Hence, we propose a novel approach to evaluate the performance of the proposed SCA algorithm. This approach can be summarized as follows:

- Firstly, by solving OP_H via the proposed SCA algorithm, we evaluate the harvested power at each user (i.e., $P_{k,H}^{(*)}$), the power splitting ratio $\{\beta_k^{(*)}\}_{k=1}^K$, the beamforming vectors and the corresponding power allocations for all user $(\{P_k^{t}\}_{k=1}^K)$, such that P_k^{t} = $||\mathbf{b}_k^{(*)}||_2^2$.
- Next, we update OP_P by including the minimum harvested power constraints to the original P-Min problem in (18). These constraints are formulated as follows:

$$(1 - \beta_k^*)\eta \sum_{j=1}^K h_k^H \mathbf{b}_j \ge \mathbf{P}_{k,H}^{(*)}, \quad \forall i \in \mathcal{K}.$$
 (35)

With these additional constraints, the modified OP_P can be now defined as

$$OP_P : \mathbf{P}_t^{min}$$

= minimize $\sum_{k=1}^K ||\mathbf{b}_i||_2^2$ (36a)

subject to SINR_k \geq SINR_k^{min}, $\forall k \in \mathcal{K}$, (36b)

$$(1 - \beta_k^*)\eta \sum_{j=1} h_k^H \mathbf{b}_j \ge \mathbf{P}_{k,H}^{(*)}, \ \forall i \in \mathcal{K}. \ (36c)$$
(8). (36d)

• Next, we reformulate *OP_P* in a semi-definite programming (SDP) form [53]:

$$\overset{\approx}{OP_P} : P^* = \min_{\{\mathbf{B}_i\}_{i=1}^K} \sum_{i=1}^K \operatorname{Tr}[\mathbf{B}_i]$$
(37a)

subject to
$$\operatorname{Tr}[H_k \mathbf{B}_i] - \gamma_i \sum_{j=1}^{i-1} \operatorname{Tr}[H_k \mathbf{B}_j]$$

$$\geq \gamma_i \sigma_k^2, \quad \forall i \in \mathcal{K}, k \leq i, \tag{37b}$$
$$\operatorname{Tr}[H_i \mathbf{B}_1] \leq \operatorname{Tr}[H_i \mathbf{B}_2]$$

$$\leq \cdots \leq \operatorname{Tr}[H_i \mathbf{B}_K], \quad \forall i \in \mathcal{K},$$
(37c)

$$(1 - \beta_k^*)\eta \sum_{i=1}^{n} \operatorname{Tr}[H_k \mathbf{B}_j] \ge \mathbf{P}_{k,H}^{(*)}$$
 (37d)

$$\mathbf{B}_i = \mathbf{B}_i^H, \mathbf{B}_i \succeq 0, \quad \forall i \in \mathcal{K},$$
(37e)

where $\mathbf{B}_i = \mathbf{b}_i \mathbf{b}_i^T$ and $\mathbf{H}_i = \mathbf{h}_i \mathbf{h}_i^T$. By relaxing rankone constraints, referred to semi-definite relaxation in the literature, OP_P turns out to be a convex problem, and thus, the solution is optimal [54] [53], [55].

The optimal power allocation and the corresponding beamforming vectors obtained by solving $\stackrel{\approx}{OP_P}$ are denoted by $\{P_k^{t\,(**)}\}_{k=1}^K$ and $\{\mathbf{b}_k^{(**)}\}_{k=1}^K$, respectively. Finally, if the beamforming obtained through solving

• Finally, if the beamforming obtained through solving $O\hat{P}_H$ and $O\hat{P}_P$ are similar, then, we can confirm that the iterative algorithm to solve the original non-convex optimization problem OP_H provides a near-optimal solution.

The simulation results confirm that the proposed algorithm with the SCA technique to solve OP_H yields a near-optimal solution with a small number of iterations.

IV. SIMULATION RESULTS

In this section, we evaluate the efficacy of the proposed technique and compare its performance against a baseline scheme. In particular, we examine the impacts of several parameters on the harvested power and verify the convergence of the proposed iterative algorithm. The CVX-package [56] is used to generate all the simulation results and the parameters considered in these simulations are summarized in Table 1. Note that for the numerical results, we have selected the simulation parameters the same as those in [35].

ZERO FORCING BEAMFORMING (ZFBF) BASELINE SCHEME

We use a ZFBF based transmission technique as a baseline scheme. For a ZFBF design with EH, the beamforming vector

TABLE 1. Parameter values used in simulations.

Parameter	Value(s)

Minimum SINR Thresholds (i.e., γ_k), $\forall k$	0 dB
Bandwidth (i.e., B_w) (MHz)	1

for each user and the corresponding PS ratio are determined such that overall harvested power is maximized [43]. The only requirement for such a system is that the number of transmit antennas should be equal to or less than the total number of users. Full details on this ZFBF design can be found in [42].

FIGURE 2. Harvested power of the MISO-NOMA system and the conventional ZFBF based MISO system against various available power levels.

2 depicts the performance of the MISO-NOMA Fig. and ZFBF based MISO systems in terms of the harvested power. As seen, the MISO-NOMA system outperforms the conventional ZFBF based MISO system. This performance enhancement is due to the following two facts. Firstly, the beamforming vectors with the ZFBF design are orthogonal to each other and the co-channel interference introduced by combining the signals at the BS is completely eliminated. Therefore, this interference mitigation significantly degrades the EH capabilities of the ZFBF based MISO systems compared to the MISO-NOMA system. Secondly, the users in MISO-NOMA system exploit the co-channel interference through superposition coding and SIC to achieve a better performance. In fact, this enhances the EH capabilities at the receivers of the MISO-NOMA system where the users take advantage of the co-channel interference to harvest energy. For example, as seen in Fig. 2, with $P^A = 20 \text{ dB}$, the harvested power at the MISO-NOMA system is around 1 (i.e., $P^H = 1$

Available power	$\mathbf{P}^A = 10 \text{ dB}$			$\mathbf{P}^A = 20 \text{ dB}$

TABLE 2. Harvested power, achieved rate, and PS ratio with different SINR requirements.

Watt), whereas the harvested power is less than 0.4 Watt with the ZFBF design.

FIGURE 3. Harvested power versus different minimum SINR thresholds.

Next, in Fig. 3, we demonstrate the impact of the minimum SINR requirements (i.e., γ_k) on the harvested power. As expected, the harvested power decreases with higher values of γ . This is due to the fact that the BS consumes more power to meet the SINR requirements, which results in a degradation of the total harvested power. An important observation is that there is a range of SINR for which the harvested energy remains more or less the same. However, with the increase of of SINR levels, the harvested power begins to drop significantly. Accordingly, the optimization problem OP_H tends to become infeasible due to insufficient power budget. With this trend, the harvested power settles down to zero, and we refer to this SINR requirement as γ^F . For example, as seen in Fig. 3, γ^F is 10 dB when $P^A = 10$ dB, whereas it reaches 12 dB with $P^A = 15$ dB.

To further understand the behaviour of OP_H with different SINR requirements, we provide more detailed results in Table 2. It can be observed that the users in the considered MISO-NOMA design can harvest power while meeting the minimum SINR requirements provided sufficient power budget is available at the BS. However, with higher SINR requirements and lower power budget P^A , the problem turns out to be infeasible as these requirements cannot be met with the available power budget. In this case, the BS alternatively chooses another option to maximize the sum rate of the system. Provided the original problem is infeasible, the users would be able to neither meet the SINR requirements nor the harvest the energy. Instead, the BS aims to maximize the sum rate of the system.

Furthermore, we investigate the impact of the users' distances on the harvested power. To study this impact, we fix the positions of the first and the second users, i.e., d_1 and d_2

FIGURE 4. Harvested power versus the distance of the strong user for different available power budgets.

at 20 meters and 30 meters, respectively, while the distance of the strongest user (i.e., d_3) is varied. The harvested power is evaluated with different values of d_3 , as shown in Fig. 4. Note that the minimum distance of the strongest user in Fig. 4 is assumed to be 2 meters. In particular, the harvested power dramatically decreases with the increase of the strong user's distance. This is due to the fact that the increase of user's distance has a direct impact on the deterioration of its channel strength. Consequently, more power will be utilized by the strongest user to meet the corresponding minimum SINR requirement. As a result, this will degrade the corresponding amount of the harvested power. As evidenced in Fig. 4, with $P^{A} = 10 \text{ dB}$, the harvested power decays dramatically from around 2 Watts at a distance of 1 meter to less than 0.1 Watt at 15 meters. Moreover, at lower P^A levels, the increasing of distance makes OP_H infeasible, and thus, the harvested power approaches zero. For example, with $P^A = 1$ dB, the harvested power becomes zero when the distance of the third user is larger than 4 meters.

Next, we study the performance of the proposed SCA algorithm to solve the harvested power maximization problem OP_H . In Table 3, we provide the harvested power at the receiver of each user (i.e., $P_i^H \forall i \in \{1, 2, 3\}$), the required transmit power, and the corresponding PS ratios obtained by solving OP_H via Algorithm 1 for a set of five random channels. In this simulation, we use the same design parameters in Table 2 to solve the power minimization problem $\overset{\sim}{OP_P}$ via SDP. The solutions of the P-Min problem $\overset{\sim}{OP_P}$ are included in Table 4. By drawing comparisons between the results presented in Tables 2 and 4, we conclude that both designs show similar results in terms of power allocations.

FIGURE 5. Convergence of the proposed algorithm when the available power $P^A = 5$ dB.

This observation confirms that the proposed SCA algorithm is an efficient approach to jointly design beamforming vectors and PS ratios.

Finally, we investigate the convergence of the proposed SCA algorithm in Fig. 5. In particular, we evaluate the convergence with the same set of five random channels considered in the previous simulations. As seen in Fig. 5, the proposed algorithm converges to the solution within a few number of iterations, i.e., less than 6 iterations.

V. CONCLUSION

In this paper, we proposed a PS based SWIPT for MISO-NOMA system and provided an optimization technique for the joint design of the beamforming vectors and the corresponding PS ratios. To overcome the non-convexity issue of the original problem, an iterative algorithm was developed with the SCA approach. Furthermore, we devised systematic approaches to examine the feasibility, the convergence, and the evaluation of the proposed SCA algorithm. The simulation results confirmed that the MISO-NOMA system outperformed the conventional ZFBF based MISO system in terms of EH capability. We examined the impact of different system parameters on the harvested power. Furthermore, we showed that the proposed SCA technique obtains the solution of the problem with only a few number of iterations.

HAITHAM AL-OBIEDOLLAH (Member, IEEE) received the B.Sc. degree from the Electrical Engineering Department, Jordan University of Science and Technology, Jordan, in 2006, and the Ph.D. degree in wireless communications from the University of York, U.K., in 2019.

He is currently an Assistant Professor with the Electrical Engineering Department, The Hashemite University, Jordan. His current research interests include non-orthogonal multiple access

(NOMA), resource allocation techniques, beamforming designs, multiobjective optimization techniques, and convex optimization theory. He was a recipient of the Kathleen Mary Stott Prize for excellence in research in Electronic Engineering from the University of York, in 2020.

KANAPATHIPPILLAI CUMANAN (Senior Member, IEEE) received the B.Sc. degree (Hons.) in electrical and electronic engineering from the University of Peradeniya, Sri Lanka, in 2006, and the Ph.D. degree in signal processing for wireless communications from Loughborough University, Loughborough, U.K., in 2009.

He was with the School of Electronic, Electrical and System Engineering, Loughborough University. He was a Teaching Assistant with the Depart-

ment of Electrical and Electronic Engineering, University of Peradeniya, in 2006. From 2006 to 2007, he was a Research Student with Cardiff University, Wales, U.K. He was an Academic Visitor with the Department of Electrical and Computer Engineering, National University of Singapore, Singapore, in 2011. From 2012 to 2014, he was a Research Associate with the School of Electrical and Electronic Engineering, Newcastle University, U.K. He is currently an Associate Professor with the Department of Electronic Engineering, University of York, U.K. His research interests include NOMA, cell-free massive MIMO, physical layer security, cognitive radio networks, relay networks, convex optimization techniques, and resource allocation techniques.

Dr. Cumanan was a recipient of an Overseas Research Student Award Scheme from Cardiff University. He is also an Associate Editor of the IEEE WIRELESS COMMUNICATIONS LETTERS and the IEEE OPEN JOURNAL OF THE COMMUNICATIONS SOCIETY.

HAYTHEM BANY SALAMEH (Senior Member, IEEE) received the Ph.D. degree in electrical and computer engineering from the University of Arizona, Tucson, AZ, USA, in 2009. He is currently a Professor of communications and networking engineering with Al Ain University, Al Ain, UAE (sabbatical leave from Yarmouk University (YU), Irbid, Jordan). He also holds a Visiting Professor position with Staffordshire University, Stoke-on-Trent, U.K. His research inter-

ests include wireless networking, with emphasis on dynamic spectrum access, cognitive radio networking, the Internet of Things, security, and distributed protocol design. He was a recipient of the Jordan Science Research Support Foundation (SRSF) Prestigious Award for Distinguished Research in ICT, in 2015, the Best Researcher Award for Scientific Colleges in YU, in 2016, and the SRSF Award for Creativity and Technological Scientific Innovation, in 2017. He has served and continues to serve on the Technical Program Committee of many international conferences.

SANGARAPILLAI LAMBOTHARAN (Senior Member, IEEE) received the Ph.D. degree in signal processing from Imperial College London, London, U.K., in 1997. He was a Visiting Scientist with the Engineering and Theory Center, Cornell University, Ithaca, NY, USA, in 1996. He was with Imperial College London, in 1999, where he was a Postdoctoral Research Associate. From 1999 to 2002, he was a Research Engineer with the Motorola Applied Research Group, U.K.,

working on various projects, including the physical-link layer modeling and performance characterization of the GPRS, EGPRS, and UTRAN. From 2002 to 2007, he was a Lecturer with King's College London, London, and a Senior Lecturer with Cardiff University, Cardiff, U.K. He is currently a Professor of digital communications and the Head of the Signal Processing and Networks Research Group, Loughborough University, Loughborough, U.K. He has authored more than 250 conference papers and journal articles in his research areas. His research interests include wireless communications, convex optimizations, game theory, blockchain, and machine learning. He is also an Associate Editor of the IEEE TRANSACTIONS ON SIGNAL PROCESSING.

YOGACHANDRAN RAHULAMATHAVAN

(Senior Member, IEEE) is currently a Senior Lecturer and a Program Director for M.Sc. Cyber Security and Data Analytics with Loughborough University, London, U.K. He is also coordinating a UK-India Education Research Initiative (UKIERI) project between Loughborough University London, IIT Kharagpur, and City University of London. His research interest includes developing novel security protocols to advance machine learn-

ing techniques to solve complex privacy issues in emerging applications, such as patient's healthcare data sharing, biometric authentication systems, identity management in cloud, and so on.

ZHIGUO DING (Fellow, IEEE) received the B.Eng. degree in electrical engineering from the Beijing University of Posts and Telecommunications, in 2000, and the Ph.D. degree in electrical engineering from Imperial College London, in 2005. From July 2005 to April 2018, he was working with Queen's University Belfast, Imperial College, Newcastle University, and Lancaster University. From October 2012 to September 2020, he has also been an Academic Visitor with Prince-

ton University. Since April 2018, he has been a Professor of communications with The University of Manchester. His research interests include 5G networks, game theory, cooperative and energy harvesting networks, and statistical signal processing. He received the Best Paper Award in IET ICWMC-2009 and IEEE WCSP-2014, the EU Marie Curie Fellowship 2012-2014, the Top IEEE TVT Editor 2017, the IEEE Heinrich Hertz Award 2018, the IEEE Jack Neubauer Memorial Award 2018, the IEEE Best Signal Processing Letter Award 2018, and the Web of Science Highly Cited Researcher 2019. He is serving as an Area Editor for the IEEE Transactions ON COMMUNICATIONS, the IEEE TRANSACTIONS ON VEHICULAR TECHNOLOGY, the *Journal of Wireless Communications and Mobile Computing*, the IEEE WIRELESS COMMUNICATION LETTERS, and the IEEE COMMUNICATION LETTERS, from 2013 to 2016.

OCTAVIA A. DOBRE (Fellow, IEEE) received the Dipl.Ing. and Ph.D. degrees from the Politehnica University of Bucharest (formerly Polytechnic Institute of Bucharest), Romania, in 1991 and 2000, respectively. From 2002 to 2005, she was with the New Jersey Institute of Technology, USA. She joined Memorial University, Canada, in 2005, where she is currently a Professor and a Research Chair. She was a Visiting Professor with the Massachusetts Institute of Technology, USA, and the

Université de Bretagne Occidentale, France. She authored or coauthored over 300 refereed articles. Her research interests include enabling technologies for beyond 5G, blind signal identification and parameter estimation techniques, as well as optical and underwater communications. She is a Fellow of the Engineering Institute of Canada. She received the Best Paper Awards at various conferences, including IEEE ICC, IEEE Globecom and IEEE WCNC. She was a Royal Society Scholar and a Fulbright Scholar. She was the General Chair, a Technical Program Co-Chair, a Tutorial Co-Chair, and a Technical Co-Chair of symposia at numerous conferences. She serves as the Editor-in-Chief (EiC) for the IEEE OPEN JOURNAL OF THE COMMUNICATIONS SOCIETY and the *IEEE Vehicular Technology Magazine*. She was the EiC of the IEEE COMMUNICATIONS LETTERS, as well as a Senior Editor, an Editor, and a Guest Editor for various prestigious journals and magazines. She was a Distinguished Lecturer of the IEEE Communications Society.
